SUMMARY

The primary aim of the Arkansas Cotton Variety Test is to provide unbiased data regarding the agronomic performance of cotton varieties and advanced breeding lines in the major cotton-growing areas of Arkansas. This information helps seed dealers establish marketing strategies and assists producers in choosing varieties to plant. In this way, the annual test facilitates the inclusion of new, improved genetic material into Arkansas cotton production. Variety adaptation is determined by evaluation of the varieties and lines at four University of Arkansas research stations located near Keiser, Clarkedale, Marianna, and Rohwer. Tests are duplicated in irrigated and non-irrigated culture at the Keiser and Marianna locations. In 2002, 37 entries were evaluated in the main test and 25 were evaluated in the first-year test. This report also includes the Mississippi County Cotton Variety Test (a large-plot, on-farm evaluation of 12 Round-up Ready varieties) and 12 other on-farm cotton variety tests conducted by the University of Arkansas Cooperative Extension Service.

Introduction

The purpose of the University of Arkansas Cotton Variety Testing Program is to provide unbiased comparisons of cotton varieties and advanced breeding lines. Data from these tests help to identify the potential adaptability of varieties to particular cotton growing regions of the state. Bourland and Benson (2000) documented several unintentional biases, which are inherent to the Arkansas cotton variety testing program. These include management associated with varieties expressing herbicide and insect resistance. The biases tend to cancel each other so that no great advantage is given to any particular variety. Recognizing the genetic differences among entries is the ultimate goal of the test, therefore, all varieties are treated the same. Within the official variety test, no specialized production inputs were implemented with respect to genetically enhanced varieties. Round-up Ready varieties, Buctril resistant varieties, Bt varieties and conventional varieties were all treated equally with respect to weed and insect control.

Lines that had not been previously tested in the Arkansas Variety Testing Program were evaluated in the 2002 1st year variety test. Lines that had been evaluated in 2001 and were re-submitted in 2002 were evaluated in the 2002 main variety test. In addition, 12 Round-up Ready varieties were evaluated in a replicated, large plot test at Manila using a standard Round-up Ready weed control program.

Materials and Methods

The 2002 Arkansas Cotton Variety Test was conducted at the Northeast Research and Extension Center at Keiser; the Delta Branch Station at Clarkedale; the Cotton Branch Experiment Station at Marianna; and the Southeast Branch Experiment Station at Rohwer. An irrigated test was conducted at each site, and a non-irrigated test was conducted at Keiser and Marianna. Cultural practices associated with the test are listed in Table 1. One on-farm variety test was conducted in Mississippi County, located in northeast Arkansas.

Environmental conditions varied across the state (Table 2). Temperatures during the 2002 production season were near the historical average (1960 - 1998), but well below the historical averages in May. Unusually cold temperatures immediately after planting delayed emergence and reduced stands at each location. As suggested by the high yield in non-irrigated tests, rainfall was above average throughout the season.

Entries were separated into those tested for the first time (1st year entries) and those having been entered in the Arkansas Cotton Variety Test the preceding year. All test sites included the same entries. All varieties were planted in two-row plots ranging in length from 40 to 50 feet. Varieties entered in the Mississippi County test at Manila were planted in 6-row plots running the full length of the field (approximately 1270 feet). The Mississippi County test included Round-up Ready and stacked gene (Round-up Ready and

Groves is a research specialist at the Southeast Branch Experiment Station; W. C. Robertson is a cotton extension specialist at the Arkansas Cooperative Extension Service.

Bollguard) varieties. All varieties in this test were treated with Round-up applied over-the-top. All tests were arranged in a randomized complete block and replicated four times. Although exact inputs varied across locations, cultural inputs at each location were generally based on University of Arkansas Cooperative Extension Service recommendations for cotton production, including COTMAN rules for insecticide termination. All plots were machine-harvested and yield per acre calculated and statistically analyzed.

Data Collected

Leaf Pubescence: Once per season, visual estimates of leaf pubescence were made in the irrigated tests at Keiser using a scale of 1 (smooth leaf) to 7 (very hairy). A full-sized leaf, ca. 5-6 nodes from plant apex, was rated for 6 plants per plot in all 4 replications.

Plant Height: Plant height measurements were collected from each variety prior to harvest. Average plant heights for varieties were determined by measuring from the soil surface to the terminal of one averaged sized plant per plot.

Lint Percentage and Fiber Data: Prior to mechanical harvest, hand-harvested samples of 50 open bolls were obtained from two replications at each location. Hand-harvested samples were collected from all four replications of the on-farm test in Mississippi County. In each test, the samples were obtained by picking all open bolls from consecutive plants. The 50-boll samples were ginned (lab gin without the use of lint cleaners) to determine lint fraction (the percentage lint to seedcotton). Fiber properties were determined using HVI classification.

Seed index: Two sets of 50 fuzzy seed were counted and weighed from the ginned seed of each 50-boll sample. If the two weights varied greatly, a third sample was taken. Two consistent weights of 50 seed were added to obtain fuzzy seed index (weight of 100 seed).

Lint Yield: Seedcotton yield per plot was converted to seedcotton yield per acre then multiplied by average lint percentage (determined by variety and location) to estimate lint per acre.

Yield Comparisons

Uncontrolled variation is inherent to collection of varietal performance data (particularly yield data). In addition to their genetic ability, variation among varieties may be due to slight differences in soil, pest or climatic conditions within a field, various interactions with specific management, or experimental error. Statistics allow users to define the degree of uncontrolled variation and to interpret data. The statistical tool used to compare means in these tests was Fisher's Protected Least Significant Difference (LSD). An LSD was calculated when the F value from ANOVA was significant. Varietal yields are considered significantly different if the difference between the mean yields of two varieties is greater than the LSD value. Differences smaller than the LSD may have occurred by chance or due to uncontrolled variation and are therefore considered not significant.

Additional estimates of variation are provided by measures of R-squared and coefficient of variation (CV). R-squared (times 100) indicates the percentage of variation that is explained by defined sources of variation (e.g. replication and variety effects within a location). Confidence in data increases as R-squared increases. Generally, the meaningfulness of difference among means is questionable when data have R-squared values of less than 50%. Also, confidence in data becomes greater as CV declines. Since CV is a function of the mean of a parameter, R-squared is a better tool for comparing the precision of different experiments.

Results

Table 1

Table 1 represents cultural inputs and production information for variety trials at Keiser (irrigated and non-irrigated), Clarkedale, Marianna (irrigated and non-irrigated), and Rohwer.

Table 2

Table 2 reports weather information for North, central, and South Arkansas during the 2002 production season.

Tables 3 – 10

Tables 3 – 10 represent the results of the Arkansas Cotton Variety Test. Varieties listed in these tables were tested the previous year in Arkansas.

Tables 11 – 18

Tables 11 – 18 represent the results of the 1st year Arkansas Cotton Variety Test. Varieties listed in these tables have never been entered in the Arkansas Cotton Variety Test.

Table 19

Ratings for incidence of *Verticillium* wilt at Clarkedale and leaf pubescence ratings at Keiser are in Table 19. Results of entries in the main test and 1st year test are reported.

Tables 20-21

Tables 20 - 21 represent two- and three-year means for entries in the main test.

Tables 22

Table 22 represents results of the Mississippi County on-farm variety test.

Acknowledgments

We express our appreciation to the directors, research specialists, and staffs at the Northeast Research and Extension Center, Delta Branch Experiment Station, Cotton Branch Station, and the Southeast Branch Station. Additionally, we would like to express our appreciation to David Wildy and Dale Wells for their efforts and support of the on-farm test in Mississippi County. Annual evaluation of cotton varieties is made possible by the work of the research assistants and technicians at these locations and by the contributions of seed companies participating in the Arkansas Cotton Variety Test.
