

# 2020 Oklahoma Replicated Agronomic Cotton Evaluation (RACE) Trial Report

cotton.okstate.edu ntokcotton.org

#### **Contributors**

Seth Byrd – Cotton Extension Specialist

Bradley Wilson – Graduate Research Assistant

Cayden Catlin – Graduate Research Assistant

Andrea Althoff - Graduate Research Assistant

Jerry Goodson - Extension Assistant, IPM

Cameron Murley – Superintendent, OPREC

Aaron Henson - Tillman Co. Extension Educator

Josh Bushong – Area Agronomist

Brian Pugh – Area Agronomist and District Program Leader

Greg Hartman – Washita and Beckham counties Extension Educator

Danny Cook – Roger Mills Co. Extension Educator

Cody Linker - Lincoln Co. Extension Educator

Gary Strickland – Greer and Jackson Co. Extension Educator and Dryland Cropping Systems Specialist

#### <u>Acknowledgements</u>

First and foremost, we would like to thank the Oklahoma cotton producers who serve as cooperators and allow us to use their land, equipment, and time to conduct these trials. These trials wouldn't be possible without their cooperation and support. Financial support for these trials was provided by the Cotton Inc. Oklahoma State Support Committee and the participating seed companies. We would like to thank Khawar Arain, Brendan Kelly, and the staff of the Texas Tech University Fiber and Biopolymer Research Institute for providing fiber classing services for these trials. And finally, we would like to thank the Oklahoma Cotton Council for their support of both the cotton agronomy program at Oklahoma State University and the entire Oklahoma cotton industry.

#### **Participating Seed Companies**

Americot/NexGen

Deltapine

Dyna-Gro Seed

FiberMax/Stoneville

PhytoGen Cottonseed

#### 2020 Season Overview

Planting conditions were generally favorable for producers in 2020, although rain events in May delayed planting on a large proportion of acreage to late May and early June. In fact, the southwest and west central locations of our 2020 RACE trials were all planted between May 29<sup>th</sup> and June 3<sup>rd</sup>. Moisture was rapidly diminishing by the end of the first week of June and hot, dry conditions dominated the primary cotton regions of the state through the remainder of the month and persisted into early July. Various significant rain events were received from mid-July into early August, although there were variations on how much and when rain fell across certain areas. For example, while the Oklahoma Mesonet site located in Elk City recorded 3.4" of rain during July, stations in Tipton and Altus each recorded 1.4". However, this was reversed in August, with only 0.85" of rain received at Elk City (over half occurring over the last 3 days of the month), compared to 2.1" at both Altus and Tipton. This July through August rain was beneficial for both dryland and irrigated cotton. It coincided with the squaring through early/peak bloom growth stages for the majority of cotton in Oklahoma which helped to reduce water stress during these critical growth stages and optimize yield.

There was an overall favorable outlook as the crop entered September, although the dry August had certainly lowered the optimism once surrounding the dryland crop. Then a cold snap struck western Oklahoma on September 9 – 10<sup>th</sup>, with daytime highs struggling to reach 60 at best, and nighttime lows flirting with freezing in many areas. Although this 2-day cold snap was followed by a return to warmer temperatures, it is likely partially to blame for the struggles many had with defoliation and boll opening later in the year. It is more likely that this short-term cold snap was an extreme sample of a larger issue, a cooler than average September with total heat unit accumulation falling 100 - 150 below average. It is likely that the slower leaf drop and boll opening, as well as the variability in micronaire or low micronaire that was common to many areas in 2020 is to blame on the weather conditions the crop experienced throughout September. There was one final hurdle to cross as an ice storm struck the area in late October, coating open bolls in ice and resulting in lint stringing out of the bolls. Luckily, there was little wind with this system or in subsequent weather events, and the actual loss of lint due to fallout was surprisingly low given the severity of the storm and the number of open bolls present on the plants. The overall feeling from 2020 was that while both yields and quality were good, maybe even great in some cases, they generally fell short of expectations that had built by the favorable conditions throughout the first three months of the season.

A total of 25 commercial varieties and one experimental variety from five seed companies were evaluated across five locations in the 2020 RACE Trials (Table 1). There were a multitude of insect and herbicide traits represented within these varieties, including both two and three gene Bt and herbicide traits (Table 2). Seasonal temperature patterns from the southwest and panhandle regions are illustrated by the monthly heat unit accumulation for 2020 compared to the 12-year average for Altus (Fig. 1) and Goodwell (Fig. 2). Dryland performance pooled across our southwest region dryland trials is presented in Table 3, while variety performance compared to the trial average of entries that were included in at least four locations is presented in Table 4. Since there are variations in variety entries across the various regions of our state, these tables provide a hint of variety performance stability for areas un-represented by our current RACE trial locations.
