Introduction

Each year, scientists at the LSU AgCenter evaluate cotton varieties at four locations that are representative of Louisiana's cotton production regions. The official variety tests (OVTs) are performed at the Red River Research Station near Bossier City, the Dean Lee Research Station near Alexandria, the Macon Ridge Research Station near Winnsboro and the Northeast Research Station near St. Joseph. Varieties are managed using practices that follow AgCenter recommendations and typify commercial operations as closely as possible. All entries within a trial are replicated four or five times and data are compiled for average performance after one and two years of testing.

Choosing Varieties

Variety selection is one of the most important decisions a cotton farmer will make for the entire growing season. The variety, and associated traits in that variety, set the stage for harvest at the time of planting. All other input decisions become supplemental after the variety is selected. Variety selection has become increasingly important since the introduction of transgenic cottons and concurrent increases in seed costs and technology fees. Moreover, variety selection is the one decision a producer makes that is not influenced by weather or other environmental factors. Therefore, choosing a high-yielding variety with acceptable fiber quality that is adapted to local growing conditions should be given careful consideration because of the tremendous importance of this decision for the entire season.

Choosing a cotton variety can be difficult, and the availability of many different transgenic traits complicates the process. The more informed the decision the better; therefore, this publication strives to provide as much information as possible to growers concerning cotton variety performance over a wide range of conditions. The information reported concerning measured

performance of cotton varieties in Louisiana should be extremely useful as a primary source of information for choosing varieties.

Producers should be mindful that OVTs can never identify the best single variety for all soils and conditions. Producers should always plant multiple varieties – selected from the top performers in the OVTs that are closest to their production region. This decision is one of the best to spread crop management activities and mitigate risk from adverse environmental conditions. There are always differences in performance of individual varieties from one year to the next. However, in most years those among the top 10% of the highest-yielding varieties generally remain there for several seasons. So the best variety for a particular farm very likely resides among the top yielders in the OVT, but no one can be certain exactly which of those top yielding varieties will be the highest yielder for the upcoming year. This is actually a good thing because it gives producers the option to select from as many as 5 to 10 varieties with different traits, knowing that any one of those may be the best for next year's crop. The majority of a grower's acreage should be devoted to proven varieties. Newer varieties should be tried on limited acreage until further testing is completed.

Fiber Properties

Fiber quality has become a more important consideration in marketing cotton and choosing varieties. As the domestic textile industry has become very limited, most U.S. cotton is being exported to foreign mills who generally demand cotton with the most consistent and highest-quality fiber properties. The quality of Louisiana cotton has been a concern in recent years, particularly with regard to high micronaire. Although premiums are small, discounts for high micronaire and other factors can be significant. Variety selection plays the largest role in fiber properties and is increasingly important for U.S. cotton to maintain and increase share in the world market.

Fiber parameters in the OVTs were determined using the same high volume instrumentation (HVI) classing system used in a USDA classing office. Physical properties including staple length (reported as the upper half mean length or UHM), fiber strength, uniformity index and micronaire were evaluated and are reported for each variety. Other fiber properties such as leaf, trash and color grades can be influenced by defoliation, ginning and seed cotton storage in modules. OVTs may not be representative of commercial operations for these fiber properties and therefore are not reported in this publication.

Using the Data

Yield should be the primary factor considered when selecting a variety, followed by fiber quality and maturity. Top yielding varieties should be considered first. There is often no statistical difference between the top yielding varieties in a given trial. The least significant difference (LSD) reported below each table is the smallest difference in yield that can be considered a "true" difference. The most important factor is not the absolute number reported for a cotton variety's yield or fiber quality. The most important question to answer is "How did a variety yield relative to other varieties in the trial"? Another important number to look for is the test average yield. Considering a variety's performance relative to the average for the entire trial will help identify varieties that are above average at a given location.

Cotton varieties should be chosen by considering their performance across several locations and years of testing. Superior performance in one year can often indicate a good variety, but superior performance over multiple years indicates consistency and reliability. Varieties are currently introduced at a rapid pace and

have shorter life spans than in the past. Data for the newest varieties are often not available for multiple years. For these new varieties that do not yet have multiyear performance records it is best to consider performance averaged across several locations during its first year of testing.

Grower experience with a past variety is important for several reasons. Cotton varieties have different growth habits and can be locally adapted to a small area. Experience with a variety should be considered, but newer varieties that perform well in OVTs should be considered as well.

Selecting Varieties

The LSU AgCenter identifies the top tier of high-yielding varieties at each location by the use of a statistical test called the least significant difference (LSD). A probability level of 5 percent is used, which means that the test correctly identifies variety performance for that location with 95 percent certainty. The group of varieties that is statistically the highest-yielding is shown in each table in bold print. To identify promising varieties that are new to the market and that have only one year of testing in the OVTs, a multilocation analysis is performed. New entries that yielded within one LSD_{0.05} of the top yielding entry in the across location analysis are in bold print.

The following table lists (alphabetically) all early and medium-maturity varieties that are among the top varieties in yield performance in the 2008 OVTs at one or more locations. Not all varieties are included in the top yielding tier at all locations; therefore, producers should review the data tables for variety performance at the closest location that is most representative of their individual farms.

Transgenic Traits

Roundup Ready. Transgenic lines are available for glyphosate tolerance, usually indicated as Roundup Ready (R or RR) or Roundup Ready Flex (RF). The Flex varieties have been commercially available since 2006 and after this year will completely replace all Roundup Ready varieties. Roundup Ready Flex varieties exhibit increased tolerance, particularly in the fruiting stage, to glyphosate applications. Roundup Ready Flex labeling allows over-the-top applications of glyphosate to Roundup Ready Flex varieties into the bloom stage and does not restrict contact with the stem for directed applications. Read and follow the label closely for specific restrictions. Moreover, growers should consult the label for specific glyphosate formulations for permitted use on Roundup Ready Flex varieties. The Roundup Ready varieties that you have grown accustomed to will still have the label restrictions for glyphosate applications.

Weed control is a major factor in producing high-yielding, high-quality cotton. Because of the increased flexibility for applying glyphosate over-the-top to Roundup Ready Flex varieties, some growers may opt to wait until weeds emerge and get some size before making applications. Waiting is not recommended, particularly for early season weed control. Early weed competition

can severely reduce yield. Glyphosate is very effective on a wide range of species, particularly when they are small. Applications should therefore be timed to weed size and not other factors. Moreover, reliance on one mode of action for weed control is not recommended and will lead to herbicide resistant weeds. Because of the recent concerns with glyphosate-resistant weeds, the use of other herbicides in addition to glyphosate in Roundup Ready Flex cotton is strongly encouraged. Consult LSU AgCenter publication 2746, 2009 Controlling Weeds in Cotton, for more information on controlling weeds in Roundup Ready Flex cotton.

Liberty link. Varieties with the designation LL in their brand name are transgenic varieties tolerant to over-the-top applications of Ignite 280 or Ignite (glufosinate). These varieties can be managed in a Liberty Link weed control program, which is covered in more detail in LSU AgCenter publication 2746, 2009 Controlling Weeds in Cotton. Liberty Link cotton is tolerant to Ignite, but will be injured by applications or drift of glyphosate. On farms or in areas where Liberty Link cotton is grown near Roundup Ready or Roundup Ready Flex cotton, care should be taken to avoid confusion of the herbicide systems and reduce the potential for mistaken applications or drift.

Bollgard and Bollgard 2. Varieties with the designation B ,BG, B2 or BG2 in their brand name are cotton lines that are tolerant to the Louisiana caterpillar pest, tobacco budworm. These varieties should not need any supplemental insecticide sprays for control of this pest. Varieties with the Bollgard 2 (B2, BG2) traits are also tolerant to the bollworm, soybean looper and beet armyworm. For these and other caterpillar pests, beware that under high and persistent populations, supplemental chemical control strategies may be necessary to provide satisfactory management. In addition, the insecticidal traits in Bollgard and Bollgard 2 varieties have no activity against noncaterpillar pests (trihips, aphids, plant bugs, stink bugs, spider mites). Those pests must be managed with conventional IPM practices.

WideStrike. Phylogen varieties with the designation W or WS2 in their brand name are cotton lines that are tolerant to the Louisiana caterpillar pests, tobacco budworm and fall armyworm. These varieties should not need any supplemental insecticide sprays for control of these pests. The other characteristics and insect management recommendations previously mentioned for Bollgard and Bollgard 2 traits remain the same for the WideStrike trait in Phylogen varieties.

Seeding Rate and Stand

Two to three plants per row foot is the ideal final plant population in 30- to 40-inch rows. To achieve this population, seeding rates should be slightly higher, based on the actual stated germination. To ensure the best seedling emergence, however, planting should still be scheduled during the most favorable conditions possible for existing and forecasted temperature and soil moisture.

Most cotton seed sold will have at least an 80 percent germination reported on the bag. This percentage is the result of the warm germination test. Field conditions, however, are typically more adverse than laboratory tests. The cool germination test can approximate adverse field conditions and is a measure of seed vigor. Results from the cool germination test are not reported on the bag but can be obtained from the seed company. Growers are encouraged to request this information. Being aware of the results of the cool germination test is more important than determining what is actually a good or bad cool germ. For example, a seed lot with 85 percent

cool germ is more vigorous than one with a 65 percent cool germ. If the 65 percent cool germ lot is planted in good, warm conditions, however, overall germination is likely to be as high as the 85 percent lot. Under adverse conditions, the 85 percent lot is likely to germinate at a much higher rate than the 65 percent lot. A somewhat arbitrary division of the cool germ test results is shown in the following table:

COOL GERMINATION %	VIGOR
>80	Excellent
65-80	Good
50-65	Acceptable – plant under good conditions
<50	Poor – most companies will not sell this seed

Remember, a cotton seed is a living organism that is used as delivery mechanism for genetic traits, transgenic technology, and often pesticide seed treatments. Care should be taken to preserve and plant high quality seed to insure adequate plant stand.

Average Performance Across Four Louisiana Locations

Lint yields in bold type within a column are not significantly different from the highest-yielding variety based on the Least Significant Difference Test at P= 0.05.

Planted May 3, 2007. Harvested October 3, 2007.

Table 16. Performance of medium maturing cotton varieties on Sharkey clay at LSU AgCenter Northeast Research Station, St. Joseph, LA in 2006 and 2007.

This material was prepared by the following
LSU AgCenter personnel:

Dr. Donald J. Boquet, Professor and Interim Cotton Specialist,
Macon Ridge Research Station

Mr. W. David Caldwell, Professor, Red River Research Station

Dr. Ernie L. Clawson, Assistant Professor, Northeast Research
Station

Dr. B. Rogers Leonard, Professor, Macon Ridge Research Station

Mr. James Hayes, Research Associate, Red River Research Station

Mr. Ivan Dickson, Cotton Fiber Lab

Assisted by the following Research Associates:
Brad Guillory, Christopher Hardy
Josh Price, John Stapp, Tim Talbot,
Brandi Woolam
