COASTAL BEND, UPPER GULF COAST, BRAZOS RIVER VALLEY,
AND SOUTHERN BLACKLANDS REGIONS OF TEXAS, 2008**

UNIFORM STACKED-GENE COTTON VARIETY TRIALS

COASTAL BEND, UPPER GULF COAST, BRAZOS RIVER VALLEY, AND SOUTHERN BLACKLANDS REGIONS OF TEXAS, 2008

Dr. Robert Lemon, Professor and Extension Agronomist – Cotton
Dr. Dan D. Fromme, Assistant Professor and Extension Agronomist
Dale Mott, Extension Program Specialist – Cotton
Texas AgriLife Extension Service
Department of Soil and Crop Sciences
College Station, Texas

Variety selection is the most important decision made during the year. Unlike herbicide or insecticide decisions that can be changed during the season to address specific conditions and pests, variety selection is made only once and that selection will dictate the management of that field for the entire season. Variety decisions should be based on genetics first, and transgenic technology second. Attention should be focused on agronomic characteristics such as yield, maturity and fiber quality when selecting varieties. Figure 1 outlines the Best Management Practices for variety selection.

Texas producers planted 4.9 million acres in 2008 which was similar acreage to 2007. In the east/south Texas regions (Coastal Bend, Upper Gulf Coast, Brazos River Valley and Blacklands) 714,000 acres were planted in 2008.

Transgenic varieties accounted for 90% of the state acreage in 2008 (87% in 2007). According to the USDA-Agricultural Marketing Service “Cotton Varieties Planted 2008 Crop” survey for the Corpus Christi Classing Office, about 21% of acres were Bollgard/Roundup Ready, 34% Bollgard II/Roundup Ready Flex, 28% Liberty Link and Liberty Link Bollgard II, and 17% Conventional cotton varieties. The most popular varieties for the region were: Fiber Max 840 B2RF – 15%, Fiber Max 832 – 14%, Fiber Max 835 LLB2 – 10%, Delta Pine 555 BGRR – 8%, Fiber Max 832 LL – 7%, Fiber Max 955 LLB2 - 7%, Fiber Max 958 LL – 4%, Deltapine 143 B2RF - 4%, Deltapine 444 BGRR – 3%, Deltapine 164 B2RF – 3%.

To assist Texas cotton producers in remaining competitive in the Coastal Bend, Upper Gulf Coast, Brazos River Valley, and the Southern Blacklands regions the Extension Cotton Agronomy program has been conducting uniform, large plot, on-farm, replicated variety trials for the past six years (Figure 2). This approach provides a good foundation of information that can be utilized to begin the decision making process.

Ten locations were planted in 2008. Counties included in the project were San Patricio, Victoria, Calhoun, Jackson, Matagorda, Wharton, Colorado, Fort Bend, Brazos and Williamson. The 2008 season was characterized as very dry through boll fill, followed by late season rainfall which was fairly common across the areas. Crop loss in the Coastal Bend due to poor stand establishment was about a 100,000 acres. Additionally, Hurricane Dolly affected the Rio Grande Valley and the Coastal Bend crop. Hurricane Dolly made landfall in the Rio Grande Valley on July 23 and devastated the Valley crop. The majority of the 91,000 acres in the Valley was lost and the northern fringe of Dolly damaged the lower Coastal Bend crop, but the crop remained harvestable. Some yield and quality loss was experienced.

Hurricane Ike made landfall near Galveston on September 13 and moved northward along the Interstate 45 corridor. Although Ike delivered serious damage to southeast Texas, the cotton crop in central Texas sustained minimal damage from rain and wind.

Commercial seed companies represented in the trials included Fibermax (FM), Stoneville (ST), Deltapine (DPL), Phylogen (PHY), Dyna-Gro (DG), and Croplan Genetics (CG). All varieties were treated with either Aeris or Avicta Complete Pak seed treatment.

Table 1 provides a list of planting and harvest dates, row spacing and plot area for each location. Subsequent tables provide a summary for each location and summaries for core varieties for the Upper Gulf Coast (Jackson, Matagorda, Wharton, Colorado, and Fort Bend Counties). Also included are results from the “Meaney Monster Cotton Variety Trial” conducted at the Corpus Christi AgriLife Research and Extension Center.

Data featured in these tables include, statistical analysis of yield, turnout, fiber quality parameters, loan and lint value results. Plot samples were ginned with a 10-saw tabletop gin with no lint cleaner. This method consistently produces higher lint turnout percentages than would be common in a commercial gin. Consequently, higher turnouts equate to lint yields which are generally higher than area-wide commercial yields. Additionally, all data were standardized to a color grade and leaf of 41 - 4. Table 2 shows numerical rankings based upon lint yield for all varieties across all locations. Only varieties that were planted in at least five locations are included.

The statistical analysis presents a general overview of the uniformity of the test conditions (soil type, cultural practices, insect damage, etc.). Trial locations with large least significant differences (LSD's) in the range of 150 to 200 lbs of lint/acre generally offer little useful information due to non-uniform conditions (higher degree of variability). The smaller the LSD, the more precise are the test results. Non-significance is represented as “NS.”

Varieties that are statistically different from one another will not have the same letter next to the corresponding number value in a column. For example, in the first table (San Patricio County) lint yields for the first three varieties are statistically similar (each variety followed by a common letter “a” designation. However, the first variety (PHY 375 WRF) is significantly higher when compared to the remaining varieties (none of which are followed by an “a” designation).

Each year review as many public and private tests within your region as possible before making decisions. Due to the annual introduction of several new varieties/technology it has become increasingly more difficult to find multi-year data. Consequently, these uniform, large plot, replicated, on-farm variety trials provide an excellent source of information.

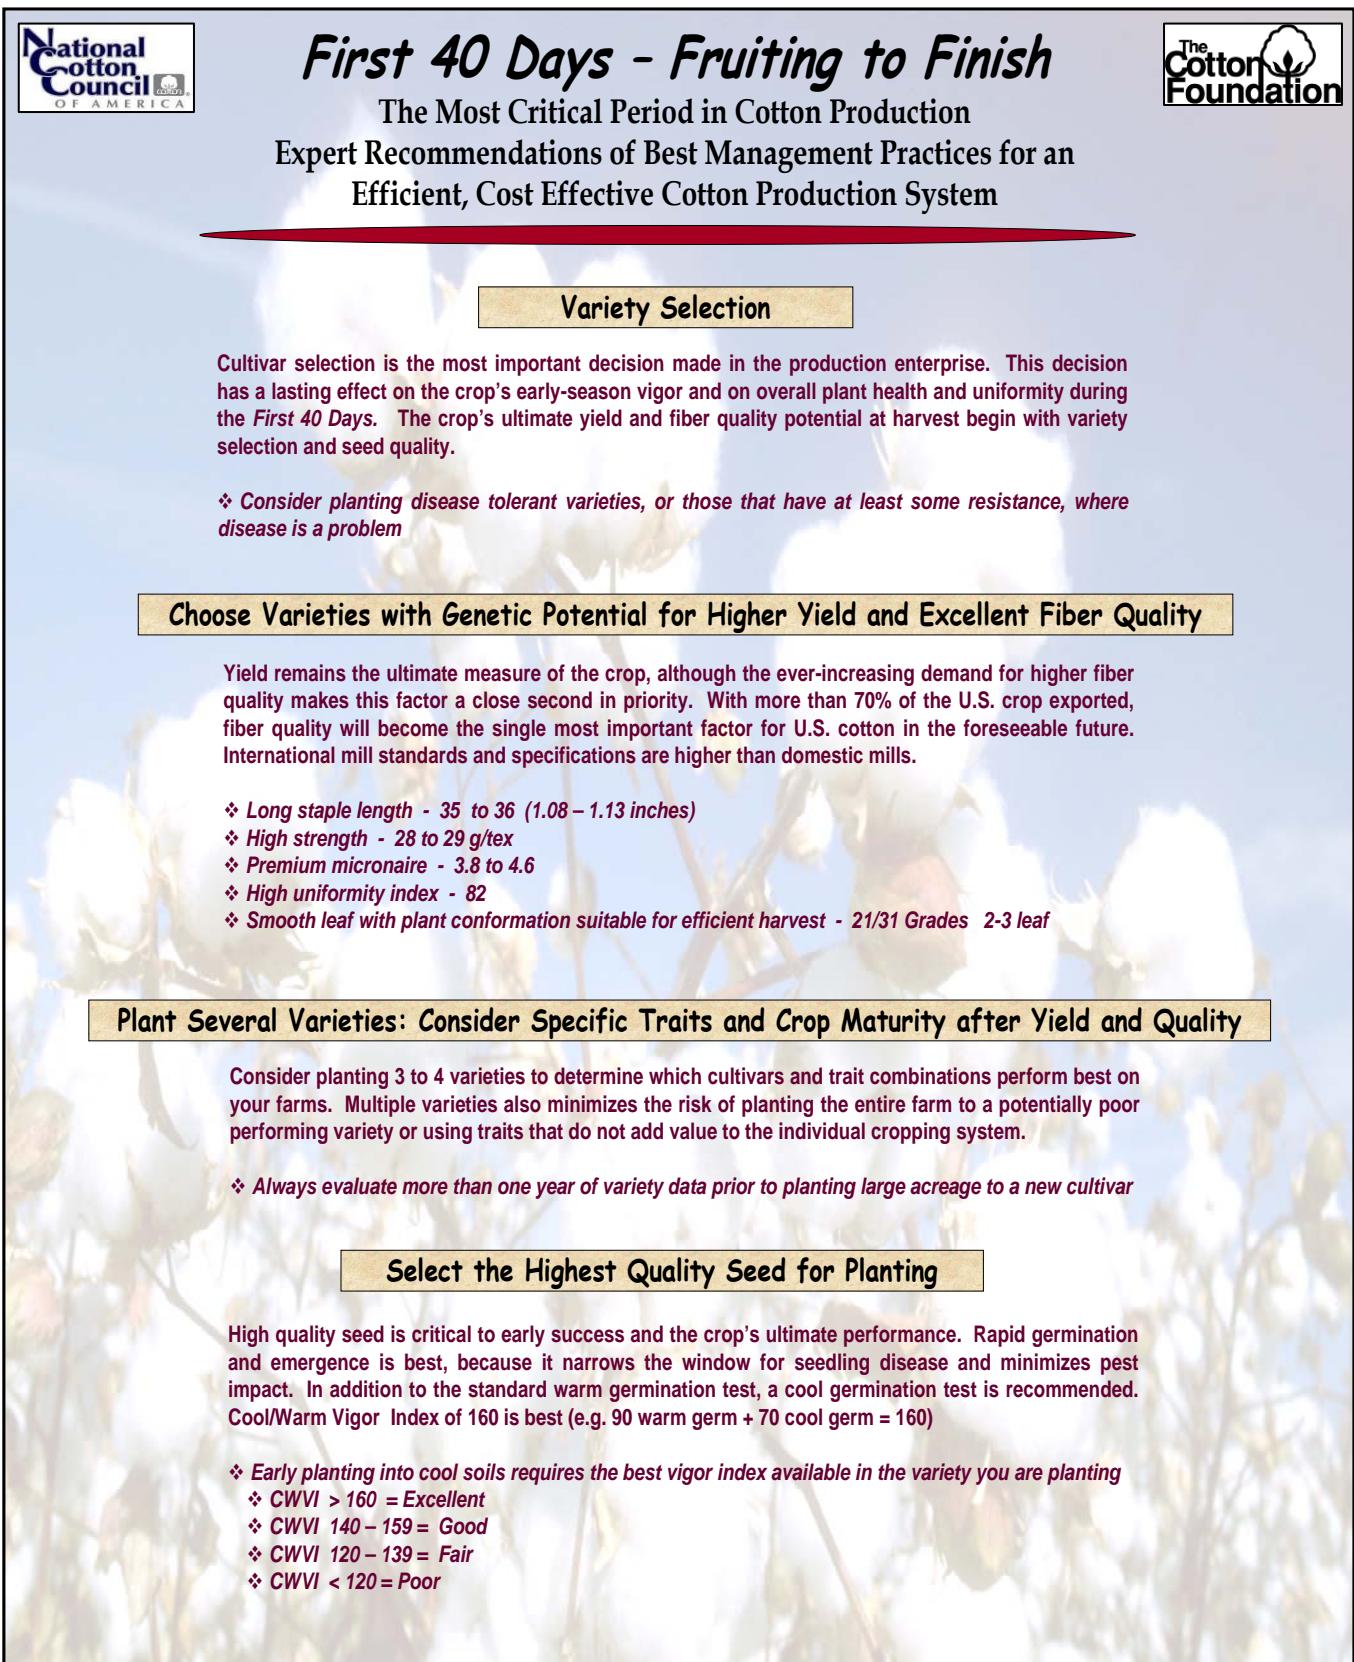

The information given herein is for educational purposes only. Reference to commercial products or trade names is made with the understanding that no discrimination is intended and no endorsement by Texas AgriLife Extension Service is implied.

Educational programs conducted by Texas AgriLife Extension Service serve people of all ages regardless of socioeconomic level, race, color, sex, religion, handicap or national origin.

Issued in furtherance of Cooperative Extension Work in Agriculture and Home Economics, Acts of Congress of May 8, 1914, as amended, and June 30, 1914, in cooperation with the United States Department of Agriculture. Edward G. Smith, Director, Texas AgriLife Extension Service, The Texas A&M University System.

National Cotton Council OF AMERICA

The Cotton Foundation

First 40 Days - Fruiting to Finish

The Most Critical Period in Cotton Production

Expert Recommendations of Best Management Practices for an Efficient, Cost Effective Cotton Production System

Variety Selection

Cultivar selection is the most important decision made in the production enterprise. This decision has a lasting effect on the crop's early-season vigor and on overall plant health and uniformity during the *First 40 Days*. The crop's ultimate yield and fiber quality potential at harvest begin with variety selection and seed quality.

- ❖ Consider planting disease tolerant varieties, or those that have at least some resistance, where disease is a problem

Choose Varieties with Genetic Potential for Higher Yield and Excellent Fiber Quality

Yield remains the ultimate measure of the crop, although the ever-increasing demand for higher fiber quality makes this factor a close second in priority. With more than 70% of the U.S. crop exported, fiber quality will become the single most important factor for U.S. cotton in the foreseeable future. International mill standards and specifications are higher than domestic mills.

- ❖ Long staple length - 35 to 36 (1.08 – 1.13 inches)
- ❖ High strength - 28 to 29 g/tex
- ❖ Premium micronaire - 3.8 to 4.6
- ❖ High uniformity index - 82
- ❖ Smooth leaf with plant conformation suitable for efficient harvest - 21/31 Grades 2-3 leaf

Plant Several Varieties: Consider Specific Traits and Crop Maturity after Yield and Quality

Consider planting 3 to 4 varieties to determine which cultivars and trait combinations perform best on your farms. Multiple varieties also minimizes the risk of planting the entire farm to a potentially poor performing variety or using traits that do not add value to the individual cropping system.

- ❖ Always evaluate more than one year of variety data prior to planting large acreage to a new cultivar

Select the Highest Quality Seed for Planting

High quality seed is critical to early success and the crop's ultimate performance. Rapid germination and emergence is best, because it narrows the window for seedling disease and minimizes pest impact. In addition to the standard warm germination test, a cool germination test is recommended. Cool/Warm Vigor Index of 160 is best (e.g. 90 warm germ + 70 cool germ = 160)

- ❖ Early planting into cool soils requires the best vigor index available in the variety you are planting
- ❖ CWVI > 160 = Excellent
- ❖ CWVI 140 – 159 = Good
- ❖ CWVI 120 – 139 = Fair
- ❖ CWVI < 120 = Poor
